

*Monsoon & Disease cases*

# DENGUE/MALARIA RISE WITH RAINFALL

BY BI BRAINS

# INTRODUCTION

The monsoon season not only brings relief and greenery but also creates conditions for diseases like dengue, malaria, and cholera to spread quickly. To understand this better, we analyzed \*rainfall, temperature, humidity, and disease cases\* in four major cities—\*Mumbai, Delhi, Bengaluru, and Hyderabad—from \*\*2009 to 2020. Our \*\*Power BI dashboard\* shows how weather patterns impact health during the rains.

# PROBLEM STATEMENT

Every year, monsoon-related diseases affect thousands of people in cities due to heavy rains, waterlogging, and changing weather. Without proper tracking of \*rainfall and disease trends\*, it becomes difficult for people and authorities to predict and prepare for outbreaks

# OBJECTIVE

- Analyze the Impact of Monsoon on Diseases
- Track Disease Trends Over Time
- Identify High-Risk Locations and Groups
- Correlate Rainfall with Disease Spread

## OVERALL SUMMARY

**AVERAGE NUMBER OF CASES: ~34.36**

**CITY WITH HIGHEST REPORTED CASES: DELHI**

## AGE GROUP IMPACT

- Seniors and Middle-Aged individuals are the most affected, showing the highest number of cases in both Male and Female categories.
- Adults follow closely, whereas Children and Youth have comparatively lower but still notable case counts.
- This implies the need for age-targeted healthcare strategies, especially for elderly and working-age populations.

## PATIENT OUTCOME & RECOVERY

- Recovery rate is extremely high at ~94%, indicating strong effectiveness of medical treatment or early diagnosis.
- However, 6% mortality still exists

## DISEASE TYPE DISTRIBUTION

- Five diseases — Dengue, Cholera, Malaria, Influenza, and Typhoid — dominate the case distribution.
- Most of these are waterborne or mosquito-borne, strongly suggesting environmental or seasonal influence, especially during monsoon periods

## YEARLY TREND OBSERVATION

- The year-wise case fluctuation remains relatively stable, but there is a noticeable peak around 2016–2018, which could signal past outbreak years.
- This predictable pattern enables forecasting and preventive planning for future outbreaks.

*Thanks for listening!*
